L.I.T.E.
Limited Information
Tetration Encryption

Darcy <a href="#">olvelieu</a>

Ben puzzleduck

# What's wrong with encryption?

- Based on computational complexity
- Everything encrypted today will one day be decryptable
- The richest can now buy decryption on demand
- SHA1 has fallen and SHA256 is in doubt
  - Quantum computing is the answer we have explore

## Can we fix it?

- An encryption scheme without dependency on computational power
- Dependant on fundamental laws of nature for security assurance
- For reference there are 1080 atoms in the universe
- Tetration creates numbers in the order of 10<sup>15,151,335</sup> using single digit inputs

## Tetration What is it?

Incrementing ++

$$-((3++)++)++=6$$

Addition + (Repeated increment)

$$-3+3 = ((3++)++)++ = 6$$

Multiplication \* (Repeated adds)

$$-3*3 = 3+3+3 = 9$$

 Exponentiation 1 / Power of ^ (Repeated multiply)

$$-3*3*3 = 3^3 = 3^3 = 3^3 = 27$$

 Tetration / superexponentiation / hyperpower 11 (Repeated exponent)

$$-31(313) = 3113 = 3^3...(27 \text{ times})...^3$$

(result is > 5gb)

#### How does it work?

- Just like private key cryptography
- Private key: eg 581147 Not capable of being stored in this universe
- Public key: subset of digits from Private key and a subset range of the result
- Encrypted data can utilise 100% of a channel to transmit a message of unknown length or values (Perfect forward security)
- Second order recursion (slow with standard computation)

## Further Details

- Example C code in GitHub repository
- Worked example in text
- Exploration of concepts
- Presentation
